Phishing and Malware

In the digital world, there are many dangers we need to be careful of. Two common threats are phishing and malware.

Phishing is when someone tries to trick you into giving personal information, like your password or credit card number. They often send fake emails or messages that look real. These messages might say there is a problem with your bank account or that you won a prize. The attacker can steal your information if you click the link and enter your details.

Malware is short for “malicious software.” It is a type of bad program that can damage your computer or steal your data. You can get malware by downloading unknown files, clicking unsafe links, or visiting dangerous websites. Some common types of malware are viruses, spyware, and ransomware. For example, a virus can slow down your computer, and ransomware can lock your files until you pay money.

To stay safe, do not click on links or download files from people you don’t know. Always check if a message is real. Look for strange spellings or suspicious email addresses. Use antivirus software and update your devices often. Being careful online helps protect your information.
